

Evaluation

Success criteria

#	Criterion	Criterion Met (Yes / Partially / No)
1	Simplified and intuitive GUI	Yes
2	User interaction with the solution does not require mouse interaction	Yes
3	Adding of tasks without specifying start or end timings	Yes
4	Adding of tasks with specifying start timing	Yes
5	Fragmentation of tasks to fit the day	Yes
6	Editing of existing tasks	Yes
7	Removal of existing tasks	Yes
8	Flexible syntax for user input fields	Yes
9	User actions can be accomplished faster than existing software	Yes

Evaluation

My solution has fulfilled criterion 1. My client has mentioned that she likes the way my solution is able to accept partial inputs in order to trigger different commands. However, she did state that many tasks look identical to one another and she would sometimes get tasks mixed up. In my opinion, another drawback being that the user would not be able to enter strings with many characters as their input could go slightly off screen. However, such issues do not necessarily limit usability.

My solution has fully implemented criterion 2 with no drawbacks. My client thoroughly enjoys the speed of the user experience and has even been able to use the program

without looking at the screen, based on pure muscle memory alone. I also believe that the criterion has been fully implemented.

For criteria 3, 4, 6, and 7, my solution has implemented the criteria as requested. However, my client has informed me that when there are no existing tasks in the day, and she adds a new task without specifying a start time, the behaviour of the task immediately starting at the absolute current time, to the minute, can feel unnatural. Though I agree that improvements can be made, I believe that an easy work-around would be to specify a fixed time for a desired time.

For criterion 5, my client has stated that the program's task fragmentation system works well, but can sometimes be unpredictable by assigning Tasks between other existing Tasks in a way my client did not expect, requiring her to delete or remove some tasks and try again. I do echo her feedback, and I believe that the feature is more suited towards her preferences, which could limit the application's use case in the future.

For criterion 8, my client particularly enjoys the ability to enter durations of a task in a simplified way compared to most programs. However, I realised that the Levenshtein distance algorithm used to predict the text input for a command tends to have a low accuracy when a user were to provide an input that was two characters or less. My client did not regard it as a significant issue, though.

Lastly, criterion 9 has been empirically proven to be fully implemented in the criterion D video.

Recommended improvements

- Make the tasks' vertical UI size based on their durations, with tasks that have a larger duration taking up more of the day, improving the readability of tasks.
- Implement colour coding features to help the user differentiate between different tasks at their discretion.
- Allow multiple tasks of the same name to be added, possibly through the use of a unique task ID system.
- Add a help command that would provide users with answers to frequently asked questions to eliminate confusion about the keyboard-focused user experience.
- Add an undo and redo option to prevent user error from disrupting their workflow and improving general quality of life.
- Allow for persistent data to prevent data loss if there is an unexpected shutdown of the solution or the operating system.
